

Welcome!

The program will begin soon.
You will not hear audio until we begin.

Building the Bridge to Future Generation of Energy Engineers

Carbon Capture, Utilization & Storage (CCUS)
Jules Reed
Global Technical Manager, Premier COREX

SPE Webinars are Sponsored by:

SPE
SPE Foundation

Why is CCUS important?

- Carbon needs to be removed from the atmosphere to meet Paris Agreement targets
- In the transition to net zero carbon emissions there is still carbon emission
- Government incentives & funding, e.g. UK £800mn, Canada \$1.8bn, Australia \$300mn
- Pilot projects including Algeria, Canada, China, Germany, Norway, Japan, UAE, UK, USA

Can current reservoir experience be used?

Similar principles are used in subsurface CCUS vs other reservoirs

- Understanding the petrophysical, geomechanical, and geological properties of the injection target formation
- Identifying the capacity of the overlying seal unit
- These are often the same reservoirs that have been previously studied and understood!

Types of study that can help with CCUS

Core analysis and petrography/mineralogy

Understand the nature of reservoirs and caprock

Dynamic properties

Corefloods for relative permeability and residual saturations

Enhanced oil recovery (EOR) – if injecting to HC reservoir

Potential to combine storage with enhanced production
Corefloods to determine microscopic sweep efficiency

Gas storage cycling

Requires study of possible hysteresis scanning curves

Rock Mechanics/ geomechanics

Understand the reservoir strength and help plan injection operations

Fluid analysis

Characterize native fluids & understand compatibility with CO₂
Understand potential for miscibility, for possible EOR

Types of study that can help with CCUS

Fluid-fluid & Rock-fluid-fluid

Compatibility studies of reactions between native rock & fluids, including scaling, incompatibility, and reaction with minerals

Flowrate dependency

Corefloods to investigate potential for fines mobilization by gaseous or dense phase (supercritical) CO₂

Operational sequence

Corefloods to look at drilling/completion/recompletion/ injection operations and identify opportunities to maximize injectivity

Simulation of thermal cycling

Reservoir temperature conditions to understand impact on rock and wellbore cement when cold fluids are introduced into a warm wellbore

Characterising and understanding the rocks

Density	Porosity	Permeability	Mineralogy
Grain size distribution	Pore size distribution	Relative permeability	Scaling
Rock mechanics	Capillary Pressure	Wettability	Fluid analysis
Rock-Fluid interactions	Residual saturations	Enhanced oil recovery	Formation damage

Characterising and understanding the rocks

- Seismic height error – ca. $\pm 15\%$ length
- Log porosity – ca. ± 3.5 porosity units (p.u.)
- Log saturation – ca. ± 10 saturation units (s.u.)

Controlled core data

- Core porosity - ± 0.5 p.u.
- Core saturation - ± 3 s.u.

Possible uncertainty reduction: 200 MM\$ - based on \$50 /ton CO₂

Measurement Type	Error (Millions USD)
Seismic length	~1300
log porosity	~200
core porosity	~50
log saturation	~300
core saturation	~100

Characterising and understanding the rocks

Longitudinal Fracturing
(no lifting support – cradle)

- Essential to understand potential core damage
 - assess sample selection
 - evaluate core analysis results

Cylindrical Shearing
(coring)

Gas Expansion (POOH)

Dendritic =
Gas Expansion

Onion-layer peel-off
Invasion ring gas-block

Shock/Handling
Damage

Chevron pattern
transit/handling
damage

Characterising and understanding the rocks

Hemipelagics Condensed	Clay - Dark olivegrey	Clay - Brown grey coarse blocky	Black Silstones	Siltstone - Green grey coarse blocky
Calcareous fines	Clay - Dark grey	Clay - Brownish red - large OM flakes	Siltstone - Deep dark brown	Clay - Olive green
Limestone - Whitish beige	Clay - Light to medium grey	Clay - Brownish grey silty - OM flakes	Siltstone - Black/oliveish	Clay - Deep dark brown
Calcareous clays	Detrital	Clay - Blackish grey silty	Siltstone - Grey/blackish bottle	Clay - Black/oliveish
Anhydrite	Clay - Bridge	Siltstones	Fines	Sandstones
Clays	Clay - Dark brown	Siltstone - Bridge	Clay - Dark brown	Loose quartz grains
Sandy	Clay - Dark olive brown	Siltstone - Dark brown	Siltstone - Dark olive brown	Sandstone
Clay - Light green sandy	Clay - Dense olive	Siltstone - Dark olive brown	Siltstone - Dense olive	Green sandstone - glauconitic
Clay - Light grey/greenish sandy	Clay - Deep dark brown	Siltstone - Brown coarse blocky	Siltstone - Brown coarse blocky	"Fracible" sandstone
Clay - White/green silty sandy	Clay - Black/oliveish	Siltstone - Green grey coarse blocky	Siltstone - Brownish grey silty - OM flakes	Green "fractile" sandstone - glauconitic
Clay - Light grey sandy	Clay - Black	Siltstone - Brown coarse blocky	Clay - Brown coarse blocky silty	"Fracible" "fractile" sandstone
Clay - Dark grey/greenish sandy	Clay - Dark red rusty	Siltstone - Brownish red - large OM flakes	Siltstone - Brown coarse blocky	Others
Clay - Greyish/brown bottle	Clay - Greyish/brown bottle	Siltstone - Brownish grey - OM flakes	Clay - Brownish red silty - large OM flakes	Average grain size
Clay - Olive/green sandy	Clay - Olive black pyrite	Siltstone - Blackish grey	Siltstone - Brownish red - large OM flakes	Highly glauconitic sandstone
Grills	Silty	Siltstone - Olive black pyrite	Siltstone - Brownish red - large OM flakes	Highly calcareous sandstone
Clay - Bridge reddish brown bottle	Clay - Green	Siltstone - Green	Clay - Dark olive brown	Highly pyritic sandstone
Mottled	Clay - Olive green	Siltstone - Olive green	Clay - Dense olive	Strongly cemented
Clay - Bridge reddish mottled	Clay - Bridge grey - large OM flakes	Siltstone - Clay/grey - large OM flakes	Clay - Green	Calcareous/sandstone - porous
Drains	Clay - Brownish green mottled	Siltstone - Clay/grey - large OM flakes	Siltstone - Green	Pyritic/sandstone - glauconitic
Clay - Dark olive green	Clay - Brown coarse blocky silty	Siltstone - Bridge/greenish - large OM flakes	Clay - Green grey coarse blocky	Blackish/mottled/blackish

- Define facies scheme, facies tops, electrofacies, hierarchical cluster analysis, rock typing, flow units
- Visualisation logs
- Architectural elements & patterns

Characterising and understanding the rocks

Core Analysis and Petrography

Seal Unit

- Seal capacity
- Strength / Threshold
- Seal integrity
- Failure stress
- Exposure properties - CO₂ impact (time-based)

Reservoir

- Current properties
- Storage capacity
- Injection capacity
- Petrophysical characterisation
- Petrographic characterisation
- Exposure properties
- CO₂ impact

Fluid analysis

- Gas / Liquid / Supercritical fluid
- Water chemistry
- Water-CO₂
- CO₂-hydrocarbon if considering EOR-CCS

Critical Point
31°C, 1070 psi (74 bar)

Core Analysis and Petrography

- Process designed to specific nature of reservoir mineralogy and fluid composition

Core Analysis and Petrography

- Determine petrophysical and dynamic rock types

Core Analysis and Petrography

- Determine petrophysical and dynamic rock types

Rock Mechanics

- Thick Walled Cylinder (TWC)
- Uniaxial Stress (Creep)
- Acoustic Travel Time
- Tensile strength

- Triaxial Compressive Strength
 - Single stage
 - Multi-stage
- Pore volume compressibility

Rock Mechanics

Stress (bar)	ΔYM	ΔPR	ΔPeak Stress
20	0.97	0.81	0.92
50	0.82	0.41	1.15
100	1.27	0.74	1.20
Residual Strength			1.04

- Rock Strength
 - Current
 - After CO₂ exposure

Triaxial Compressive Strength

Core Analysis and Petrography

- How does exposure to CO₂ impact on reservoir & seal properties?

What all this can tell us

- Modelling CO₂ injection needs data input
 - Storage capacity
 - Saturation vs injection volume
 - Saturation vs height
 - Reservoir integrity
 - Wellbore stability
 - Exposure impact
 - Fluid properties

What about well operations?

Formation Damage

- ✚ Reservoirs material (rock & fluids) can react with operational fluids, injection fluid, changes in conditions (P & T)
- ✚ Reactions can reduce permeability and production/injection
- ✚ Reducing risk & Add value by identifying the change mechanisms

Why is this relevant to CCUS?

- ✚ Well operations will be carried out
- ✚ CO₂ can react with reservoir material
- ✚ CO₂ can amplify scaling risk

Wellbore operations

- ✚ What is the CO₂ going to be injected into?
 - ✚ New well, convert existing well?
- ✚ What are we going to do prior to injection?
- ✚ Could these operations impact upon injectivity?
- ✚ Can damage be avoided?

How to examine this

- ✚ Reservoir-conditions laboratory simulations
- ✚ Examine planned well operations or well history + planned conversion
- ✚ Measure impact, identify & visualise alterations
- ✚ Use data to confirm operations or identify potential for improvement

Reservoir-conditions coreflood simulations

Case study: drilling CCUS well

Injection Issues

- Does CO₂ injection cause fines migration or other change mechanisms?
- Is this due to rate/viscosity, chemistry, or a combination?
- Is there a difference when injecting gaseous, liquid or supercritical CO₂?

How to examine this

- Reservoir-conditions laboratory simulations
- Interaction with representative reservoir material
- “Flowrate dependency”, fines migration, injection
- Are there changes, what changes, caused by what?
- Is any impact upon injection inevitable, is it acceptable, or can it be avoided/removed?

Examining carbon dioxide safely

Permeability vs injection rate

Case Study: fines migration

Compatibility & scaling

- Is there a risk of precipitation due to injection?
- Is it caused by chemistry, change in conditions, or both?
- What precipitates and is it avoidable or treatable?

How to examine this

- Range of options, typically computer modelling + coreflood laboratory simulations
- Model various conditions & mixes – likelihood & scale types
- Inject using representative core and fluids – what happens and where
- Use data to put scaling risk into context & help decide whether avoiding or remedial actions may be necessary

Scale prediction modelling

Visualising changes

A moderate amount of high intensity change along the length of the core sample caused by changes in density, possibly due to accumulation of fines and/or fluid retention.

An abundant amount of high intensity change at the formation end of the core sample caused by changes in density, possibly due to accumulation of re-distributed/back-produced fines and/or fluid retention.

After dilution and application followed by desorbent

Treating damage

- Was the mechanism identified?
- Is treatment required to avoid or remediate?
- Do the treatments work as intended or have unexpected side-effects?

How to examine this

- How and when will the treatment options be deployed?
- Repeat studies with treatment - does it have an impact?
- Important to understand & visualise the impact as well as any unexpected results
- If necessary, review candidates and repeat

Understanding treatment fluid impact

- Severe reduction in permeability
 - Approx. 60%
- What caused that alteration?

New visualisation techniques show us more

Was the treatment suitable?

- Combination of changes = severe reduction in permeability (ca. 60%)
- Clay:
 - some removal,
 - some accumulation
- Inhibitor:
 - fluid retention, particularly associated with clay minerals
- Overall:
 - reduction in pore volume
- Result:
 - suitable chemical?

Final thoughts

- Vast subsurface experience, and how to examine them, exists. Use it!
- Reservoir chemistry & properties and human interventions define CO₂ injectivity
- Understanding behaviour at every process stage reduces uncertainty to reduce risk and add value
- As CCUS evolves, so will techniques. Chemical and microbial sequestration may move to reservoirs. There is vast experience in advanced testing available
- As always: there is no substitute for quality laboratory data using representative materials!
